# Lecture Assignment Project Exam Help a Streams

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

Prof. Michael R. Lyu

Computer Science & Engineering Dept.

The Chinese University of Hong Kong

# Motivation

- In many data mining situations, we know the entire data set in advance
- Stream Management when the input rate is controlled
  - Google queries
  - Twitter and Facebook status updates
- We can think of the data as infinite and non-stationary (the distribution changes over time)

Interest over time ?

# The Stream Model

- Input tuples (e.g., [user, query, time]) enter at a rapid rate, at one or more input ports
- The system can access the entire stream accessibly
- How do you make critical decisions about the stream using a limited amount of (secondary) memory?

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Problems on Data Streams

- Types of queries one wants on answer on a stream:
  - Sampling data
    - Construct <https://eduassistpro.github.io/>
  - Queries over sliding window
    - Number of items of type  $x$  in the last  $k$  elements of the stream
  - Filtering a data stream
    - Select elements with property  $x$  from the stream

# Problems on Data Streams

- Types of queries one wants on answer on a stream:
  - Counting di
    - Number of <https://eduassistpro.github.io/> last  $k$  elements of the stream [Add WeChat edu\\_assist\\_pro](#)
  - Estimating moments
    - Estimate avg./std. dev. of last  $k$  elements
  - Finding frequent elements

# Applications (1)

- Mining query streams
  - Google wants to know what queries are more frequent to
- Mining click
  - Yahoo! wants to know <https://eduassistpro.github.io/> s pages are getting an unusual number of hits in the past hour
- Mining social network news feeds
  - E.g., look for trending topics on Twitter, Facebook

# Applications (2)

- Sensors Networks
  - Many sensors feeding into a central controller
- Telephone c
  - Data feeds into customer settlements between tel companies
- IP packets can be monitored at a switch
  - Gather information for optimal routing
  - Detect denial-of-service attacks

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Sampling from a Data Stream

- Since we cannot store the entire stream, one obvious approach is to store a sample
- Two different
  - Sample a fixed number of elements in the stream (say 1 in 10)
  - Maintain a random sample of fixed size over a potentially infinite stream
    - At any “time”  $t$  we would like a random sample of  $n$  elements. For all  $t$ , each of  $n$  elements seen so far has equal prob. of being sampled

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Sampling a Fixed Proportion

- Problem 1: Sampling fixed proportion
- Scenario: Search engine query stream
  - Stream of tuples
  - Answer queries: <https://eduassistpro.github.io/> in did a user run the same query on two different days
  - Have space to store  $1/10^{\text{th}}$  of query stream
- Naive solution:
  - Generate a random integer in  $[0..9]$  for each query
  - Store the query if the integer is 0, otherwise discard

# Problem with Naive Approach

- Simple question: What fraction of queries by an average user are duplicates?
- Suppose each user issues  $s$  queries on the heap and  $d$  queries twice (total of  $sp + dp$  queries) where the probability of a query being a duplicate is  $p$ 
  - Correct answer:  $dp^2 / (sp + dp^2 + 2p(1-p)d)$
  - Sample will contain  $sp$  of the single queries and  $2dp$  of the duplicate queries at least once
  - But only  $dp^2$  pairs of duplicates
    - $dp^2 = p * p * d$
  - Of  $d$  "duplicates"  $2p(1-p)d$  appear once
    - $2p(1-p)d = ((p*(1-p)) + ((1-p)*p)) * d$
  - So the sample-based answer is:  $dp^2 / (sp + dp^2 + 2p(1-p)d)$

# Problem with Naive Approach

- A concrete example:
  - Query stream: 1, 2, 3, 4, 5, 6, 7, 7, 8, 8
  - Sample 50% <https://eduassistpro.github.io/> s case
  - Correct ans <https://eduassistpro.github.io/> re duplicates
  - If our sample is 1, 2, 3, 4 [Add WeChat: edu\\_assistpro](https://eduassistpro.github.io/) are duplicates
  - If our sample is 6, 7, 7, 8, 8, then 67% are duplicates
  - What is the expectation of fraction of duplicates if we use sample-based method?

Answer: 1/9

Solution?

# Solution: Sample Users

- Pick  $1/10^{\text{th}}$  of **users** and take all their searches in the sample
- Use a hash function on the user name or use **10 buckets**
- Generalized: Pick  $1/d^{\text{th}}$  of users, we need to use **d buckets**

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Generalized Solution

- Stream of tuples with keys:
  - Key is some subset of each tuple's components
    - E.g., tuple  $i$  key is user
  - Choice of  $k$  <https://eduassistpro.github.io/> ation
- To get a sample of size  $a$  [Add WeChat edu\\_assist\\_pro](#):
  - Hash each tuple's key uniformly into  $b$  buckets
  - Pick the tuple if its hash value is at most  $a$   
( $h(x) = 1, 2, \dots, a$ )

# Maintaining a Fixed-size Sample

- Problem 2: Fixed-size sample
- Suppose we need to maintain a sample  $S$  of size exactly  $s$  ( $s$  is fixed out of  $S=100$  space)  
<https://eduassistpro.github.io/>  
Add WeChat [edu\\_assist\\_pro](#)
- E.g., main memory size const
- Why? Don't know length of stream in advance
  - In fact, stream could be infinite
- Suppose at time  $t$  we have seen  $n$  items
  - Ensure each item is in the sample  $S$  with equal prob.  $s/n$

# Solution: Fixed Size Sample

- Algorithm:

- Store all the first  $s$  elements of the stream to  $S$
- Suppose we have seen  $n$  elements, and now the  $n+1^{\text{th}}$  element arrive
  - With prob.  $s/n+1$ , pick the  $n+1^{\text{th}}$  element. Else discard it
  - If we picked the  $n+1^{\text{th}}$  element, replace one of the  $s$  elements in the sample  $S$ , picked uniformly at random

- **Claim:** This algorithm maintains a sample  $S$  with the desired property, i.e., each item is in the sample  $S$  with equal prob.

# Proof: By Induction

- We prove this by induction:
  - Assume that after  $n$  elements, the sample contains each element seen so far with prob.  $s/n$
  - We need to <https://eduassistpro.github.io/> element  $n+1$  the sample maintains th  
Add WeChat edu\_assist\_pro
    - Sample contains each element seen so far with prob.  $s/(n+1)$
  - Obviously, after we see  $n=s$  elements the sample has the wanted property
    - Each out of  $n=s$  elements is in the sample with prob.  $s/s=1$

# Proof: By Induction

- After  $n$  elements, the sample  $S$  contains each element seen so far with probability  $s/n$
- Now element
- For elements remaining in  $S$  is
- At time  $n$  tuples in  $S$  were there with prob.  $s/n$
- Time  $n \rightarrow n+1$  tuple stayed in  $S$  with prob.  $n/(n+1)$
- So prob. tuple is in  $S$  at time  $n+1 =$

# Counting Bits (1)

- Problem:

- Given a stream of 0s and 1s

- Be prepare

- many 1's in

Assignment Project Exam Help

f the form How

<https://eduassistpro.github.io/>

$e k \leq N$

- Obvious solution:

Add WeChat edu\_assist\_pro

- Store the most recent  $N$  bits

- When a new bit comes in, discard the  $N+1^{\text{st}}$  bit

# Counting Bits (2)

- You cannot get an exact answer without storing the entire window
- **Real Problem** **not afford to** store  $N$  bits?  
– E.g., we are processing 1 streams and  $N = 1$  billion
- But we're happy with an approximate answer

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# An Attempt: Simple Solution

- How many 1s are in the last  $N$  bits?
- Simple solution that does not really solve our problem:  
Uniformity assignment Project Exam Help
- Maintain 2 counters <https://eduassistpro.github.io/>
  - $S$ : number of 1s so far
  - $Z$ : number of 0s so far
- How many 1s are in the last  $N$  bits?  $N \cdot S / (S + Z)$
- But, what if stream is non-uniform?
  - What if distribution changes over time?

# DGIM Method

- Store  $O(\log^2 N)$  bits per stream

Assignment Project Exam Help

- Gives approx <https://eduassistpro.github.io/> ver off by more than 50%

Add WeChat edu\_assist\_pro

- Error factor can be reduced by a fraction  $> 0$ , with more complicated algorithm and proportionally more stored bits

# Idea: Exponential Windows

- Solution that doesn't (quite) work:
  - Summarize exponentially increasing regions of the stream,  $\log$
  - Drop small  $r$  at the same point as a larger region

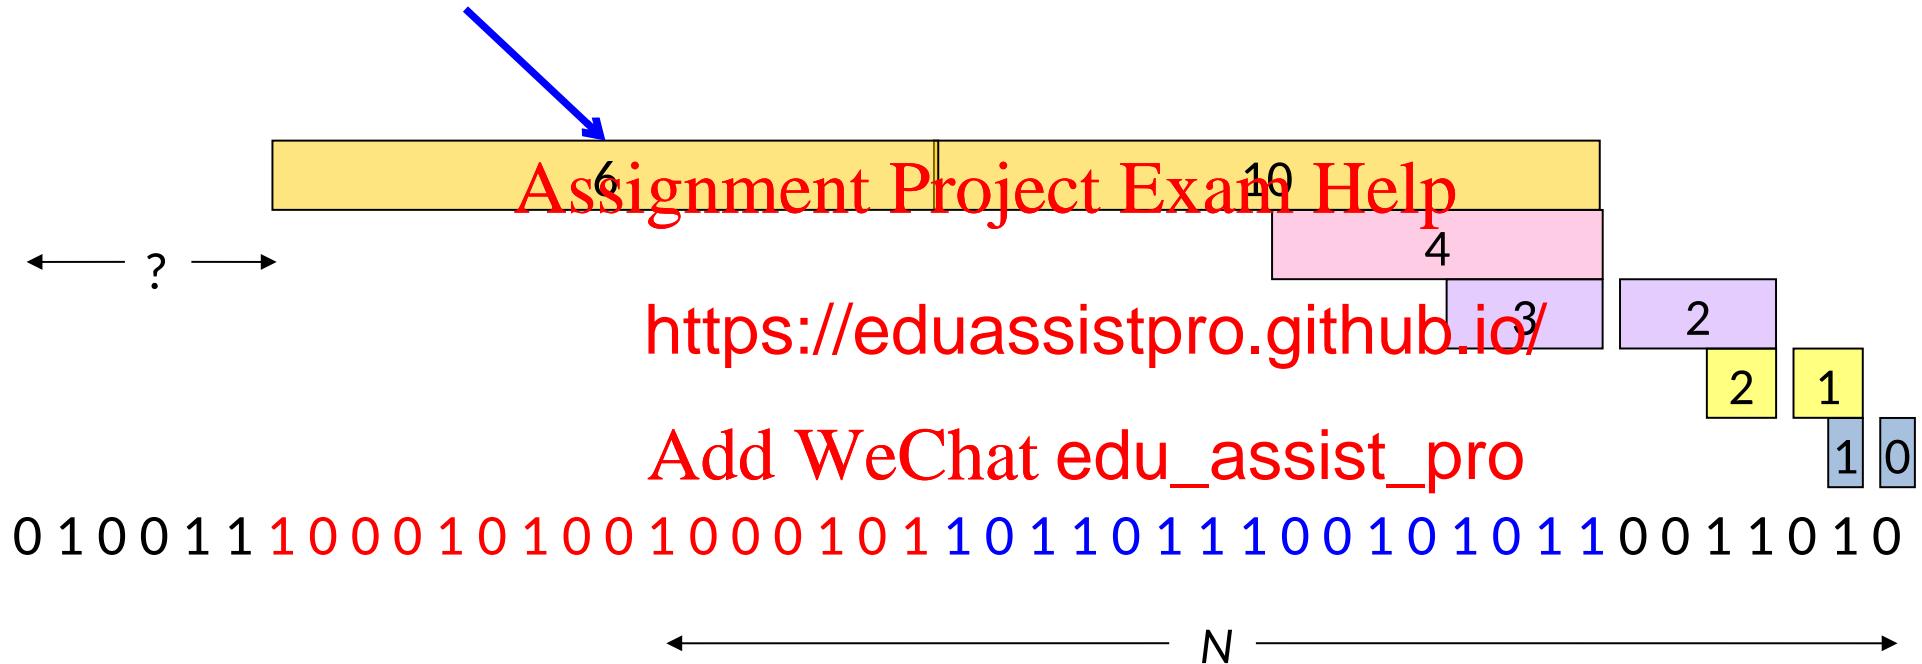

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# An Exponential Window Example

Window of width 16 has 6 1s

We can construct the count of the last  $N$  bits, except we're not sure how many of the last 6 are included.

# What's Good?

- Stores only  $O(\log^2 N)$  bits
  - $O(\log N)$  counts of  $\log N$  bits each
- Easy update as more bit
- Error in count no greater than the number of 1s in the “unknown” area

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# What's Not So Good?

- As long as the 1s are fairly evenly distributed, the error ratio due to the unknown region is small – no m
- But it could be in the unknown area at the end
- In that case, the error is unbounded

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Fixup: DGIM Method

- Instead of summarizing fixed-length blocks, summarize blocks with specific numbers of 1s
  - Let the block size increase exponentially
- When there are few 1s, block sizes stay small, so errors are small

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WhatsApp edu\_assist\_pro

# DGIM: Timestamps

- Each bit in the stream has a *timestamp*, starting 1, 2, ...
- Record times (the window size), so we can find the timestamp in  $O(\log_2 N)$

Assignment Project Exam Help

<https://eduassistpro.github.io/>

vant

Add WeChat edu\_assist\_pro

# DGIM: Buckets

- A *bucket* in the DGIM method is a record consisting of:
  1. The times  $[t_{\text{begin}}, t_{\text{end}})$  in  $[0, \log N)$  bits]
  2. The number of 1s in the bucket beginning and end:  $[O(\log \log N), O(\log \log N))$  bits]
- **Constraint on buckets:** Number of 1s must be a power of 2
  - That explains the  $O(\log \log N)$  in (2)

# Representing a Stream by Buckets

- Either **one** or **two** buckets with the same power-of-2 number of 1s
- Buckets do not have timestamps
- Buckets are sorted by size
  - Earlier buckets are not smaller than later buckets
- Buckets disappear when their end-time is  $> N$  time units in the past

Assignment Project Exam Help

<https://eduassistpro.github.io/>

# Example: Bucketized Stream

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

## Properties we maintain:

- Either **one** or **two** buckets with the same power-of-2 number of 1s
- Buckets do not overlap in timestamp
- Buckets are sorted by size

# Updating Buckets – (1)

- When a new bit comes in, drop the last (oldest) bucket if its end-time is prior to  $N$  time units before the cu

Assignment Project Exam Help

<https://eduassistpro.github.io/>

- 2 cases: Current bit is 0 o

Add WeChat edu\_assist\_pro

- If the current bit is 0, no other changes are needed

# Updating Buckets – (2)

- If the current bit is 1:
  - Create a new bucket of size 1, for just this bit
    - End timest
  - If there are <https://eduassistpro.github.io/> of size 1, combine the oldest two into a bucket of size 2
  - If there are now three buckets of size 2, combine the oldest two into a bucket of size 4
  - And so on ...

# Example

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# How to Query?

- To estimate the number of 1s in the most recent  $N$  bits:
  - Sum the size of the last bucket
  - Add half the size of the last bucket
- **Remember:** we don't know how many 1s of the last bucket are still within the window

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Example: Bucketized Stream

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# In-Class Practice 1

- Go to [practice](#)

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Error Bound: Proof

- Suppose the last bucket has size  $2^r$
- Then by assuming  $2^{r-1}$  of its 1s are still within the window, of at most  $2^{r-1}$
- Since there is at least one of each of the sizes less than  $2^r$ , the sum is no less than  $1 + 2 + 4 + \dots + 2^{r-1} = 2^r - 1$
- Thus, error ratio is at most  $2^{r-1} / (2^r - 1) \approx 50\%$

# Extensions (For Thinking)

- Can we use the same trick to answer queries “How many 1s in the last  $k$ ?” where  $k < N$ ?  
[Assignment Project Exam Help](https://eduassistpro.github.io/)
- Can we handle the case where the stream is not bits, but integers, and we want the sum of the last  $k$ ?  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro

# Reducing the Error

- Instead of maintaining 1 or 2 of each size bucket, we allow either  $r-1$  or  $r$  for  $r > 2$ 
  - Except for  $t$  buckets; we can have any number of those
- Error is at most  $1/r$
- By picking  $r$  appropriately, we can tradeoff between number of bits and the error

# Outline

- Sampling from a Data Stream
- Queries over a (long) Sliding Windows
- **Filtering Data**
- Counting Distinct Elements
- Computing Moments
- Counting Itemsets

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Filtering Data Streams

- Each element of data stream is a **tuple** (a finite list of elements)
- Given a list of keys  $S$
- How to determine if elements of stream have keys in  $S$ ?  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro
- **Obvious solution:** Hash table
  - But suppose we **do not have enough memory** to store all of  $S$  in a hash table
    - E.g., we might be processing millions of filters on the same stream

# Applications

- **Example: Email spam filtering**
  - We know 1 billion “good” email addresses
  - If an email c...ese, it is NOT spam
- **Publish-subscribe syste**
  - People express interest in certain sets of keywords
  - Determine whether each message matches user’s interest

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# First Cut Solution – (1)

- Given a set of keys  $S$  that we want filter
- Create a **bit array**  $B$  of  $n$  bits, initially all 0s
- Choose a hash function  $h$  with range  $[0, n)$
- Hash each  $m$  and set that bit to 1, i.e.  $B[h(m)] = 1$
- Hash each element  $a$  of the stream and output only those that hash to bit that was set to 1
  - Output  $a$  if  $B[h(a)] == 1$

# First Cut Solution – (2)

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

- Creates false positives but no false negatives
  - If the item is in  $S$  we surely output it, if not we may still output it

# First Cut Solution – (3)

- $|S| = 1$  billion email addresses  
 $|B| = 1\text{GB} = 8$  billion bits
- If the email address  $a$  hashes to a bucket  $t$ , it surely hashes to a bucket  $t$  with  $t[a] = 1$ , so it always gets through (no false negatives)
- Approximately  $1/8$  of the bits are set to 1, so about  $1/8^{\text{th}}$  of the addresses not in  $S$  get through to the output (**false positives**)
  - Actually, less than  $1/8^{\text{th}}$ , because more than one address might hash to the same bit

# Analysis: Throwing Darts

- More accurate analysis for the number of **false positives**
- **Consider:** If  $n$  equally likely targets, the probability that a target gets at least one dart is  $1 - (1 - \frac{1}{n})^n$
- **In our case:**
  - Targets = bits/buckets
  - Darts = hash values of items

# Analysis: Throwing Darts – (2)

- We have  $m$  darts,  $n$  targets
- What is the probability that a target gets at least one dart

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Analysis: Throwing Darts – (3)

- Fraction of 1s in the array  $B$  == probability of false positive ==

Assignment Project Exam Help

- **Example:** <https://eduassistpro.github.io/>  
dar  
– Fraction of 1s in  $B$  = 0.1  
– Compare with our earlier estimate:  $1/8 = 0.125$
- Can we improve this error?

# Bloom Filter

- Consider:  $|S| = m$ ,  $|B| = n$
- Use  $k$  independent hash functions
- **Initialization:**
  - Set  $B$  to all 0
  - Hash each element using  $h$  function, set (for each )
- **Run-time:**
  - When a stream element with key  $x$  arrives
    - If for all , then declare that  $x$  is in  $S$
    - Otherwise discard the element  $x$

Assignment Project Exam Help

<https://eduassistpro.github.io/>

Add WeChat edu\_assist\_pro

# Counting Distinct Elements

- **Problem:**

- Data stream consists of a universe of elements chosen from

- Maintain a <https://eduassistpro.github.io/> of distinct elements seen so far

- **Obvious approach:**

- Maintain the set of elements seen so far

# Applications

- How many different words are found among the Web pages being crawled at a site?  
Assignment Project Exam Help  
– Unusually low word count could indicate artificial page  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro
- How many different Web pages does each customer request in a week?

# Using Small Storage

- **Real Problem:** What if we do not have space to store the complete set?  
Assignment Project Exam Help
- Estimate the count in a <https://eduassistpro.github.io/> way  
Add WeChat edu\_assist\_pro
- Accept that the count may be in error, but limit the probability that the error is large

# Flajolet-Martin Approach

- Pick a hash function  $h$  that maps each of the  $n$  elements to **at least**  $\log_2 N$  bits
- For each stream  $a$  be the number of trailing zeros in the binary representation of  $h(a)$ 
  - $r(a)$  = position of first 1 bit in the right
- Record  $R$  = the maximum  $r(a)$  seen
  - $R = \max_a r(a)$ , over all the items  $a$  seen so far
- **Estimated number of distinct elements =  $2^R$**

# Why It Works

- The probability that a given  $h(a)$  ends in at least  $r$  0s is  $2^{-r}$

–  $h(a)$  has been chosen at random

– Probability that a given  $h(a)$  ends in at least  $r$  0s is  $2^{-r}$

- If there are  $m$  different elements, the probability that  $R \geq r$  is  $1 - (1 - 2^{-r})^m$

Prob. all  $h(a)$ 's end in fewer than  $r$  0s.

Prob. a given  $h(a)$  ends in fewer than  $r$  0s.

# Why It Works – (2)

- Note:
- Prob. of NOT finding a tail of length  $r$  is:
  - If  $r > m$ , then prob.  $\rightarrow 0$ 
    - as  $r \rightarrow \infty$ ,  $\frac{1}{2^r} \rightarrow 0$
    - So, the probability of finding a tail of length  $r$  tends to 1
  - If  $r \leq m$ , then prob. tends to  $\frac{1}{2^r}$ 
    - as  $r \rightarrow \infty$ ,  $\frac{1}{2^r} \rightarrow 0$
    - So, the probability of finding a tail of length  $r$  tends to 1
- Thus,  $m$  will almost always be around  $m$ .

# Why It Doesn't Work

- $E[2^R]$  is actually infinite
  - Probability halves when  $R \rightarrow R + 1$ , but value doubles
- Workaround involves using many hash functions and getting m <https://eduassistpro.github.io/>
- How are samples combine
  - Average? What if one very large value?
  - Median? All values are a power of 2
  - Solution:
    - Partition your samples into small groups
    - Take the average of groups
    - Then take the median of the averages

Add WeChat edu\_assist\_pro

# Generalization: Moments

- Suppose a stream has elements chosen from a set of  $N$  values

Assignment Project Exam Help

<https://eduassistpro.github.io/>

- Let  $m_a$  be the number of times value  $a$  occurs

Add WeChat edu\_assist\_pro

- The  $k^{th}$  *moment* is

# Special Cases

- $0^{\text{th}}$  moment = number of different elements
  - The problem just considered
- $1^{\text{st}}$  moment =  $\frac{\sum \text{values}}{\text{number of elements}}$ 
  - Easy to compute
- $2^{\text{nd}}$  moment = *surprise number* = a measure of how uneven the distribution is

# Example: Surprise Number

- Stream of length 100; 11 values appear
- **Item counts:** 10, 9, 9, 9, 9, 9, 9, 9, 9, 9, 9  
Surprise # = <https://eduassistpro.github.io/>
- **Item counts:** 90, 1, 1, 1, , 1, 1, 1  
Surprise # = 8,110

# AMS Method

- Works for all moments
- Gives an unbiased estimate
- We'll just construct <https://eduassistpro.github.io/>  
Assignment Project Exam Help
- Based on calculation of many random variables  $X$ :
  - For each random variable  $X$ , we store  $X.e$  and  $X.val$
  - Each random variable represents one separate item
  - Note this requires a count in main memory, so number of  $X$ s is limited

# One Random Variable

- Assume stream has length  $n$
- Pick a random time to start, so that any time is equally likely
- Let the chose  $a$  in the stream
- $X = n * ((\text{twice the number of } a \text{ in the stream starting at the chosen time}) - 1)$ 
  - **Note:** store  $n$  once, count of  $a$ s for each  $X$

# Expected Value of X

- 2<sup>nd</sup> moment is

- $E(X) = \sum_{\text{all times } t} n * (\text{twice the number of times the stream element } e \text{ appears from that time on}) - 1$

=

=

Group times by  
the value seen

Time when the  
last *a* is seen

Time when  
the penultimate  
*a* is seen

Time when  
the first *a*  
is seen

# Combining Samples

- One random variable only represent one sampled item; we should do many concurrent samples
- Compute as many variables  $X$  as can fit in available memory
- Average them in groups
- Take median of averages
- Proper balance of group sizes and number of groups assures not only correct expected value, but expected error goes to 0 as number of samples gets large

# Problem: Streams Never End

- We assumed there was a number  $n$ , the number of positions in the stream
- But real stream is unbounded, so  $n$  is a variable – the number of elements seen so far

# Stream Never End: Fixups

- The variables  $X$  have  $n$  as a factor – keep  $n$  separately; just hold the count in  $X$
- Suppose we can only store  $k$  counts. We must throw some  $X$ 's out
  - Objective: each starting time  $t$  is kept with probability  $k/n$
  - Solution: (fix-size sampling!)
    - Choose the first  $k$  times for  $k$  variables
    - When the  $n^{\text{th}}$  element arrives ( $n > k$ ), choose it with probability  $k/n$
    - If you choose it, throw one of the previously stored variables out, with equal probability

# Appendix

- Sampling from a Data Stream
- Queries over a (long) Sliding Windows
- Filtering Data
- Counting Distinct Elements
- Computing Moments
- Counting Itemsets

# Counting Itemsets

- **New Problem:** Given a stream, which items appear more than  $s$  times in the window?  
Assignment Project Exam Help
- **Possible solution:** stream of baskets as 0 or 1 per item  
<https://eduassistpro.github.io/>  
Add WeChat edu\_assist\_pro
  - 1 = item present; 0 = not
  - Use DGIM to estimate counts of 1s for all items

# Extensions

- In principle, you could count frequent pairs or even larger sets the same way
  - One stream
- Drawbacks:

Assignment Project Exam Help

# Exponentially Decaying Windows

- Exponentially decaying windows: A heuristic for selecting likely frequent itemsets
  - What are “c” and “N”?
    - Instead of <https://eduassistpro.github.io/> in last N elements
    - Compute a smooth aggregate over the whole stream
- If stream is  $a_1, a_2, \dots$  and we are taking the sum of the stream, take the answer at time  $t$  to be:
  - $c$  is a constant, presumably tiny, like  $10^{-5}$  or  $10^{-6}$
  - When new  $a_t$  arrives: Multiply current sum by  $(1-c)$  and add  $a_t$

# Example: Counting Items

- If each is an “item” we can compute the **characteristic function** of each possible item  $x$  as an exponentially decaying window (E.D.W.).
  - That is: <https://eduassistpro.github.io/>
    - where if , and 0 otherwise
  - Imagine that for each item a binary stream (1 ...  $x$  appears, 0 ...  $x$  does not appear)
  - New item  $x$  arrives:
    - Multiply all counts by  $(1-c)$
    - Add +1 to count for  $x$
- Call this sum the “**weight**” of item  $x$

# Sliding Versus Decaying Windows

Important property: Sum over all weights is

=

# Counting Items

- Suppose we want to find those items of weight  $> \frac{1}{2}$ 
  - Important parameter  $p$  is =  
Assignment Project Exam Help  
<https://eduassistpro.github.io/>
- Thus:
  - There cannot be more than  $p$  items with weight of  $\frac{1}{2}$  or more  
Add WeChat edu\_assist\_pro
- So,  $p$  is a limit on the number of movies being counted at any time

# Extension to Larger Itemsets

- Count (some) itemsets in an E.D.W.
  - **Problem:** Too many itemsets to keep counts of all of them in memory
- When a basket <https://eduassistpro.github.io/>
  - Multiply all counts by 1
  - For uncounted items in  $B$ , create new count
  - Add 1 to count of any item in  $B$  and to any itemset contained in  $B$  that is already being counted
  - Drop counts  $< \frac{1}{2}$
  - Initiate new counts (next slide)

# Initiation of New Counts

- Start a count for an itemset if every proper subset of  $S$  had a count prior to arrival of basket  $B$ 
  - Intuitively: If all subsets of  $S$  are being counted this means they are, thus  $S$  has a potential to be “hot”
- Example
  - Start counting  $\{i, j\}$  iff both  $i$  and  $j$  were counted prior to seeing  $B$
  - Start counting  $\{i, j, k\}$  iff  $\{i, j\}$ ,  $\{i, k\}$ , and  $\{j, k\}$  were all counted prior to seeing  $B$

Add WeChat edu\_assist\_pro

# How Many Counts?

- Counts for single items  $< (2/c) * (\text{average number of items in a basket})$
- Counts for large sets
- But we are conservative starting counts of large sets
  - If we counted every set we saw, one basket of 20 items would initiate 1M counts
